

# Data Representation

# External vs. Internal Representation

- **External representation:**
  - Convenient for programmer
  - Decimal (base 10)
- **Internal representation:**
  - Actual representation of data in the computer's memory:  
Always binary (1's and 0's)

# Binary representation (base 2)

- On a computer all data is stored in binary
- Only two symbols: 0 and 1
- Each position is called a *bit*
- *Bits take up space*
- 8 bits make a *byte*
- *Example of a 4-bit number*

Represent  $15_{10}$  in binary using positional encoding

- Actually the data is voltages
- We use the abstraction:
  - High voltage: 1 (true)
  - Low voltage: 0 (false)

Represent  $15_{10}$  in binary using positional encoding

$1111$

# Positional encoding for non-negative numbers

- Each position represents some power of the base
- Decimal (Base 10), Digits (0-9)
- Binary (Base 2), Digits (0,1)
- Hex (Base 16), Digits (0-9, A-F)

# Unicode

- Universal character encoding (extends ASCII to handle other languages)

```
>>> chinese = '\u4e16\u754c\u60a8\u597d!'
>>> print(chinese)
世界您好!
```

- Includes all ASCII characters using the same ascii encoding

```
>>> print('\u0048\u0049')
